It is difficult to train a dog or a cat, since they are emotional, and they don't always know what they are feeling, or what to feel. We, as pet owners, are the only ones who can tell when our pet is upset. So when he cries, yelps, whimpers, howls, or howls back, when he tries to hide or hide from us, or even he just gets tired or upset, then it is time to call the vet and get your pet's tail between his legs. The most important thing is to make sure your pet is ok before going to the vet, so that you can get your vet to put your pet on her table and take a quick look at your pet before seeing your pet. A good vet will not let you go in the examination room unless your pet is ok, and ready to be taken to her office. That way she can look at your pet without you having to take your pet into the examination room. It is stressful for the vet, the animal, and the owner. For children, this is the time to look for a dog in the shelter or a cat in a foster home. You may be able to get to know your new pet before you commit to adopting the pet. You may be able to keep the animal in your house for a couple of months before you decide to give the animal a permanent home. Most small animal vets are reluctant to see sick animals. They fear it will take a long time and interfere with their schedule. A good animal shelter or animal rescue

I'm running into some performance problems, and I'm not sure how to solve them. I've got an Entity in Core Data, with several instances of NSManagedObjects stored in the Entity. The NSManagedObjects have some relationships between them (a Person is related to a Trip). The way I have it set up now, I store a Person object in the trip, and then have a relationship between Person and Trip. But when I want to look up the trip for a particular Person object, I have to go through all the Persons for the trip, and perform a query on all the trips. This seems to be pretty inefficient, and I have no idea how I can solve it better. If I were doing this in SQL, I'd have a person table with a trip_id field, and then a trip table with a person_id field. What would be the best way to set this up in Core Data? A: If you can store Trip entities, then you can just get the trip directly from the store, and then filter in your Person instances to return the appropriate ones. If you are reluctant to store Trip entities (maybe because of performance or other reasons) and cannot do so, then you should probably query the Person instances first to determine what trips they're a part of. You can do this with an NSFetchRequest and then merge the results with a KVC join. For example: NSFetchRequest *fetchRequest = [NSFetch 2d92ce491b
